RockawayX vaults under attack

riskdep on a mainnet fork, step by step · alerts on Telegram

The question we answer

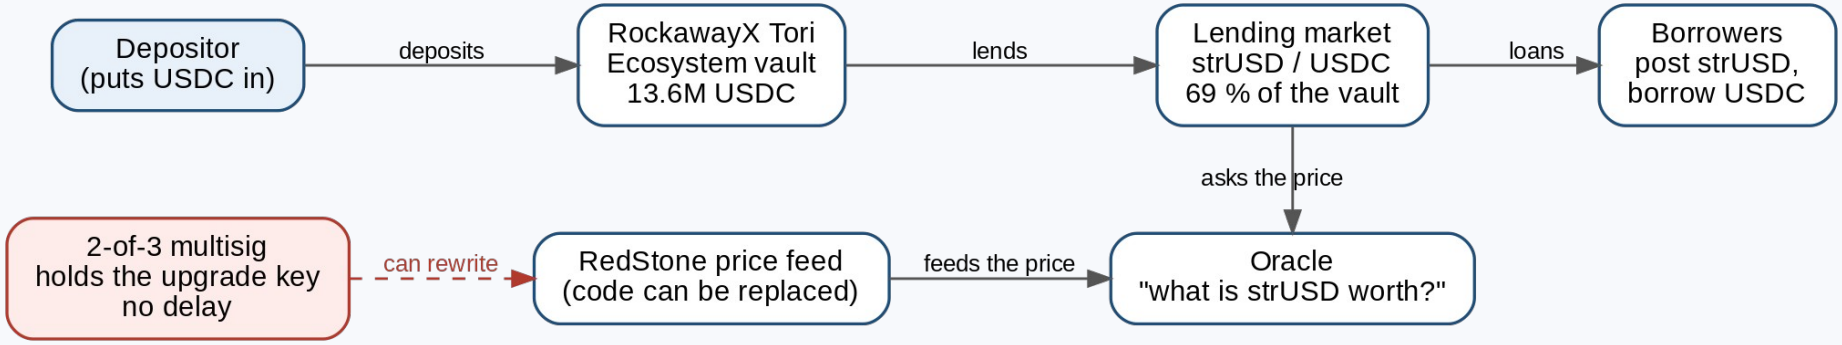

One deposit hides a chain of other contracts and people

When one link breaks: what does it do to my position, and how fast?

Leaving costs something for sure; staying may cost more

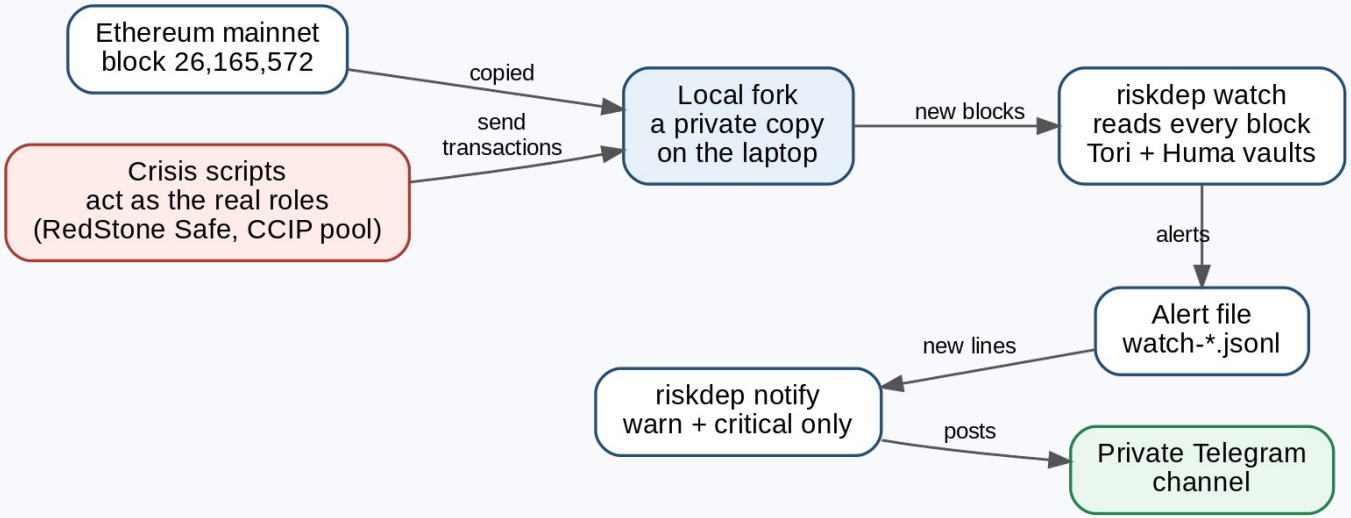

riskdep finds the chain, watches it, and says stay or exit

What a deposit really depends on

- Your USDC goes into the vault, which lends it to borrowers who post strUSD
- Those loans are safe only while the oracle prices strUSD correctly
- The oracle reads a RedStone feed whose code can be replaced
- Two signatures out of three are enough to do it, with no delay

How the demo works

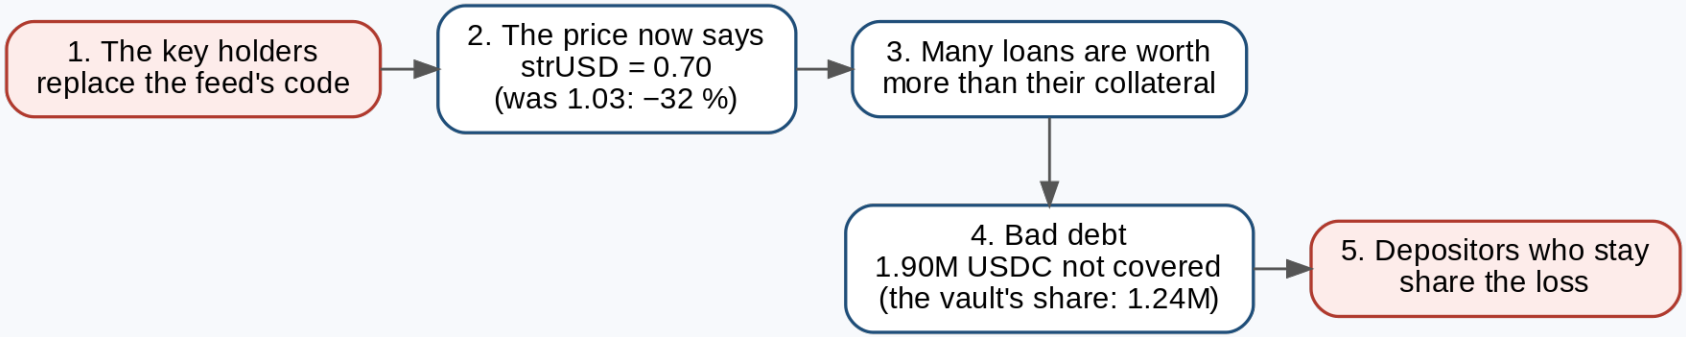

- A fork is a private copy of Ethereum on the laptop
- Scripts act as the real key holders: nothing real is touched
- riskdep reads every new block, as it would on mainnet
- Only real risks (warn and critical) reach Telegram

The words, in plain language

Word	What it means
Vault	A pool of deposits lent out by a curator
Oracle	The contract that tells the market what collateral is worth
Bad debt	A loan worth more than what backs it: someone loses
Multisig	A wallet that needs several signatures (here 2 of 3)
Fork	A private copy of the blockchain, for rehearsing a crisis
warn / critical	Something changed / money is being lost now

Act 1 · The price feed is rewritten

- RedStone's multisig swaps the code of the strUSD price feed
- The new code says strUSD is worth 0.70 instead of 1.03
- Loans become bigger than their collateral: 1.90M USDC of bad debt
- Until it is written off, whoever stays in the vault carries it

Act 1 · What riskdep said

Alert	Level	In plain words
Admin.Upgraded	critical	The code behind the price changed
Oracle moved −32 %	warn	The collateral lost a third of its value
UnrealisedBadDebt	critical	1.90M USDC of loans no longer covered
ExitQueue	critical	In a rush to the exit, this depositor gets stuck
OracleDivergence	warn	The oracle is 32 % below the market price
OracleImpact	critical	The loss, and the decision: EXIT

Act 1 · Stay or exit?

Stay

Loses 454,103 USDC: its share of the bad debt

Waits for the debt to be written off

Exit now: riskdep's verdict

2,374,262 USDC can leave at full value

The loss falls to 293,378 USDC

2,620,422 USDC cannot leave yet

Is this a hack?

Who sends the upgrade	What it is	Effect
Someone with 2 stolen keys	A hack	Price set by the attacker
The real signers, by mistake	A bad upgrade	Same damage
The real signers, announced	Maintenance	Nothing bad

Act 2 · Coins from nowhere

- The bridge pool creates 15M PST, +7 % of the supply
- Nothing backs these new coins
- The oracle reads a rate, not the supply: it still says 1.138
- riskdep flags the mint itself, in the same block

Reading a Telegram alert

One message per incident; red (critical) rings the phone

First line: the vault and what happened, in plain words

Then the loss and the decision: EXIT or STAY

Details folded underneath: tap to open

A 'What to do' button opens the runbook

What to remember

A position depends on people and code you never see

riskdep names them, watches them and prices the damage

Each alert says what happened, what it costs and what to do

It cannot tell a hack from an upgrade: it flags both

Limits: a simulated crisis, prices read block by block
